Introduction

Class-agnostic counting count the number of objects with user-specified exemplars. This is crucial for applications like crowd control in public security and car counting in traffic management.

Class-agnostic counting count based on the input image and user-specified exemplars.

Motivation: Class-agnostic methods often err due to variations in object size, shape, and color, as well as high density and occlusion. To address this, we propose a framework that integrates human feedback to correct these errors.

Shape Variation

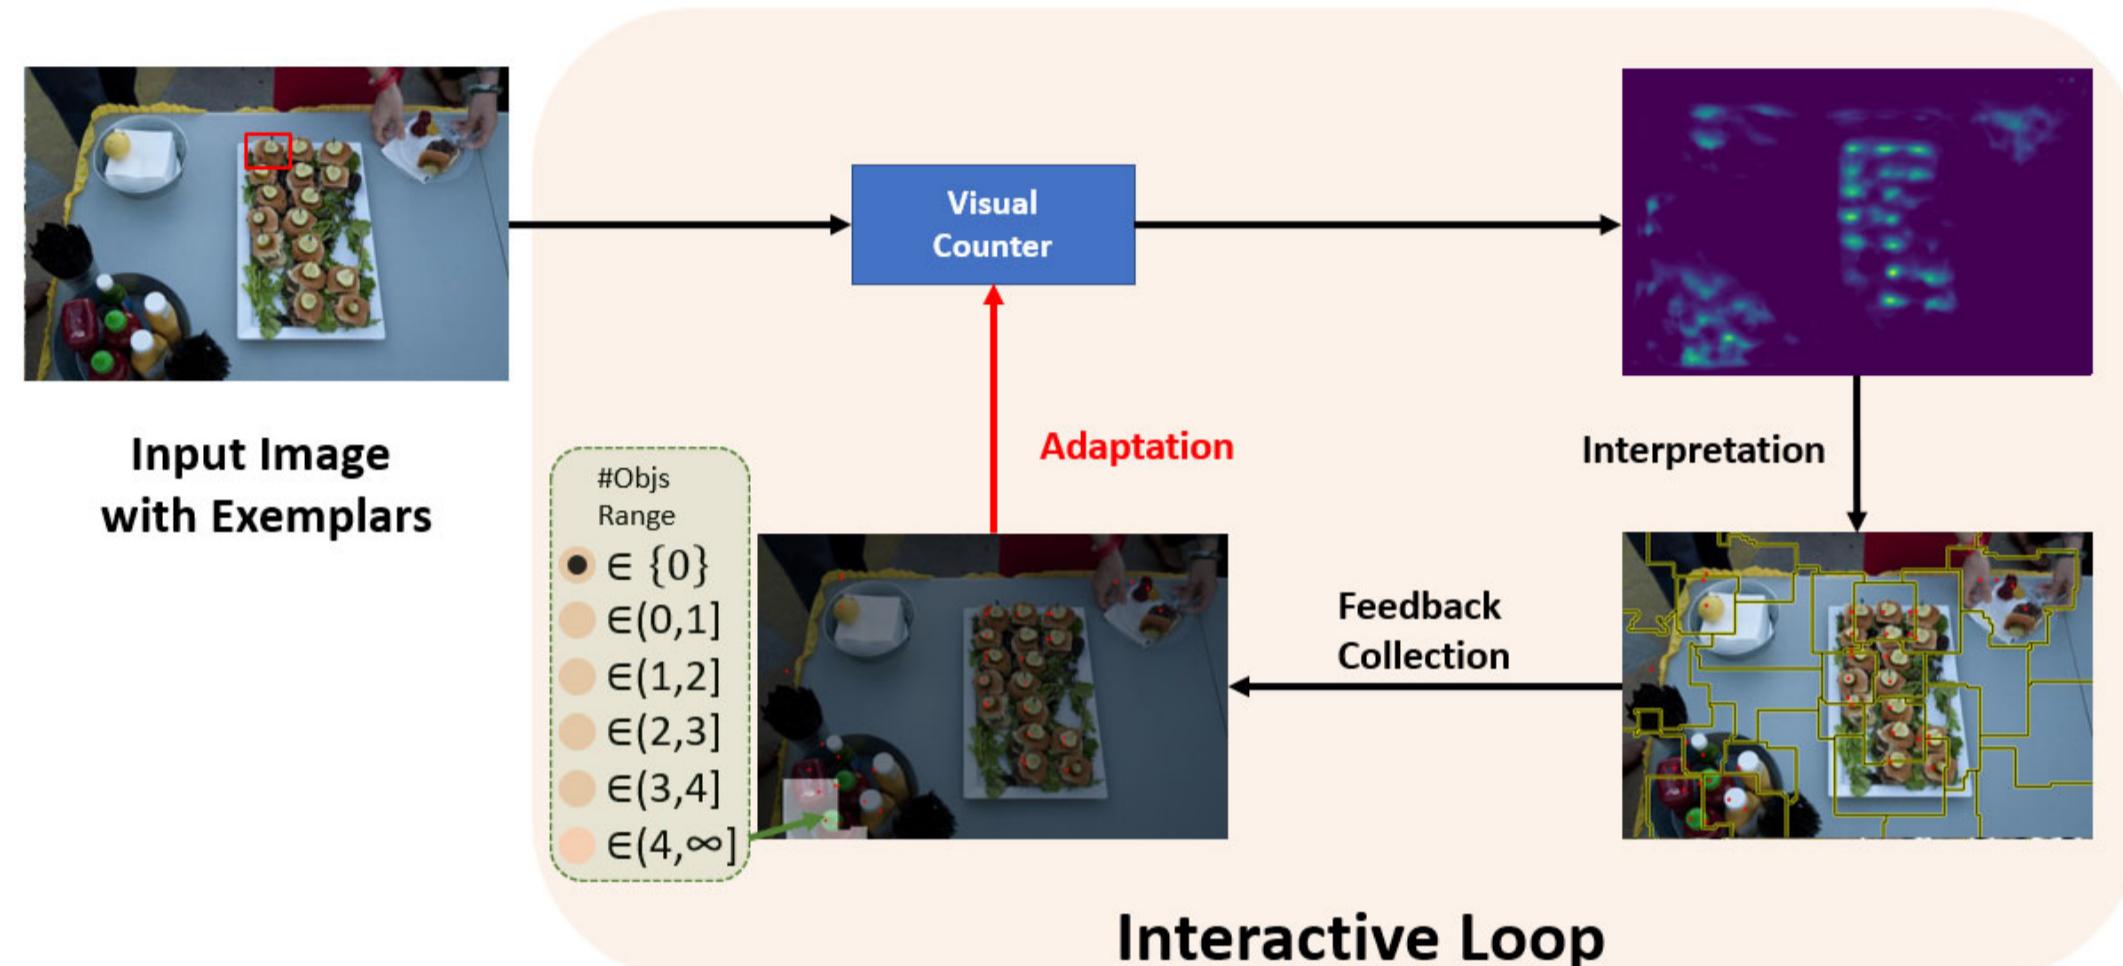

Large Density

Occlusion

Main Contributions:

- **Interpretation:** interpret the predicted density map into an intuitive result.
- **Feedback collection:** A feedback collection scheme that requires minimal user effort.
- **Adaptation:** An effective adaptation approach that incorporates the user's feedback to improve the visual counter.

Method Details

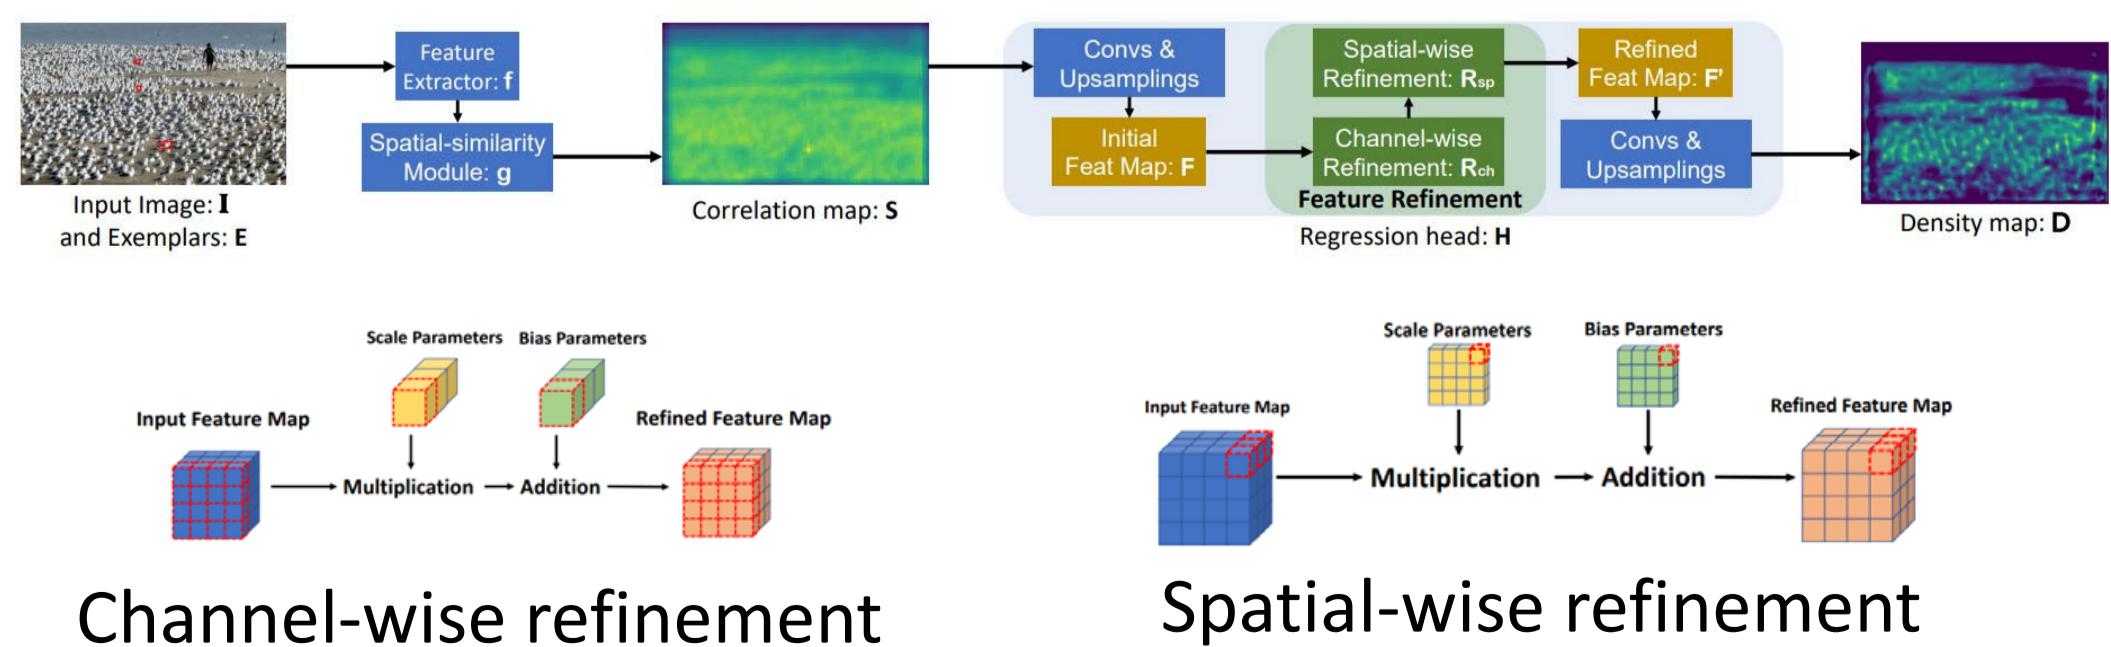

- **Interpretation:** IPSE density map segmentation by iteratively select pick & expand to minimize:

$$h(R) = \frac{|R_s - \lceil R_s - \frac{1}{2} \rceil|}{\max(1, \lceil R_s - \frac{1}{2} \rceil)} + \frac{\max(0, T_l - R_a)}{T_l} + \lceil \max(0, R_s - C) \rceil$$

- **Feedback collection:** User provide feedback by select a region then given the range of #Objects in the region.

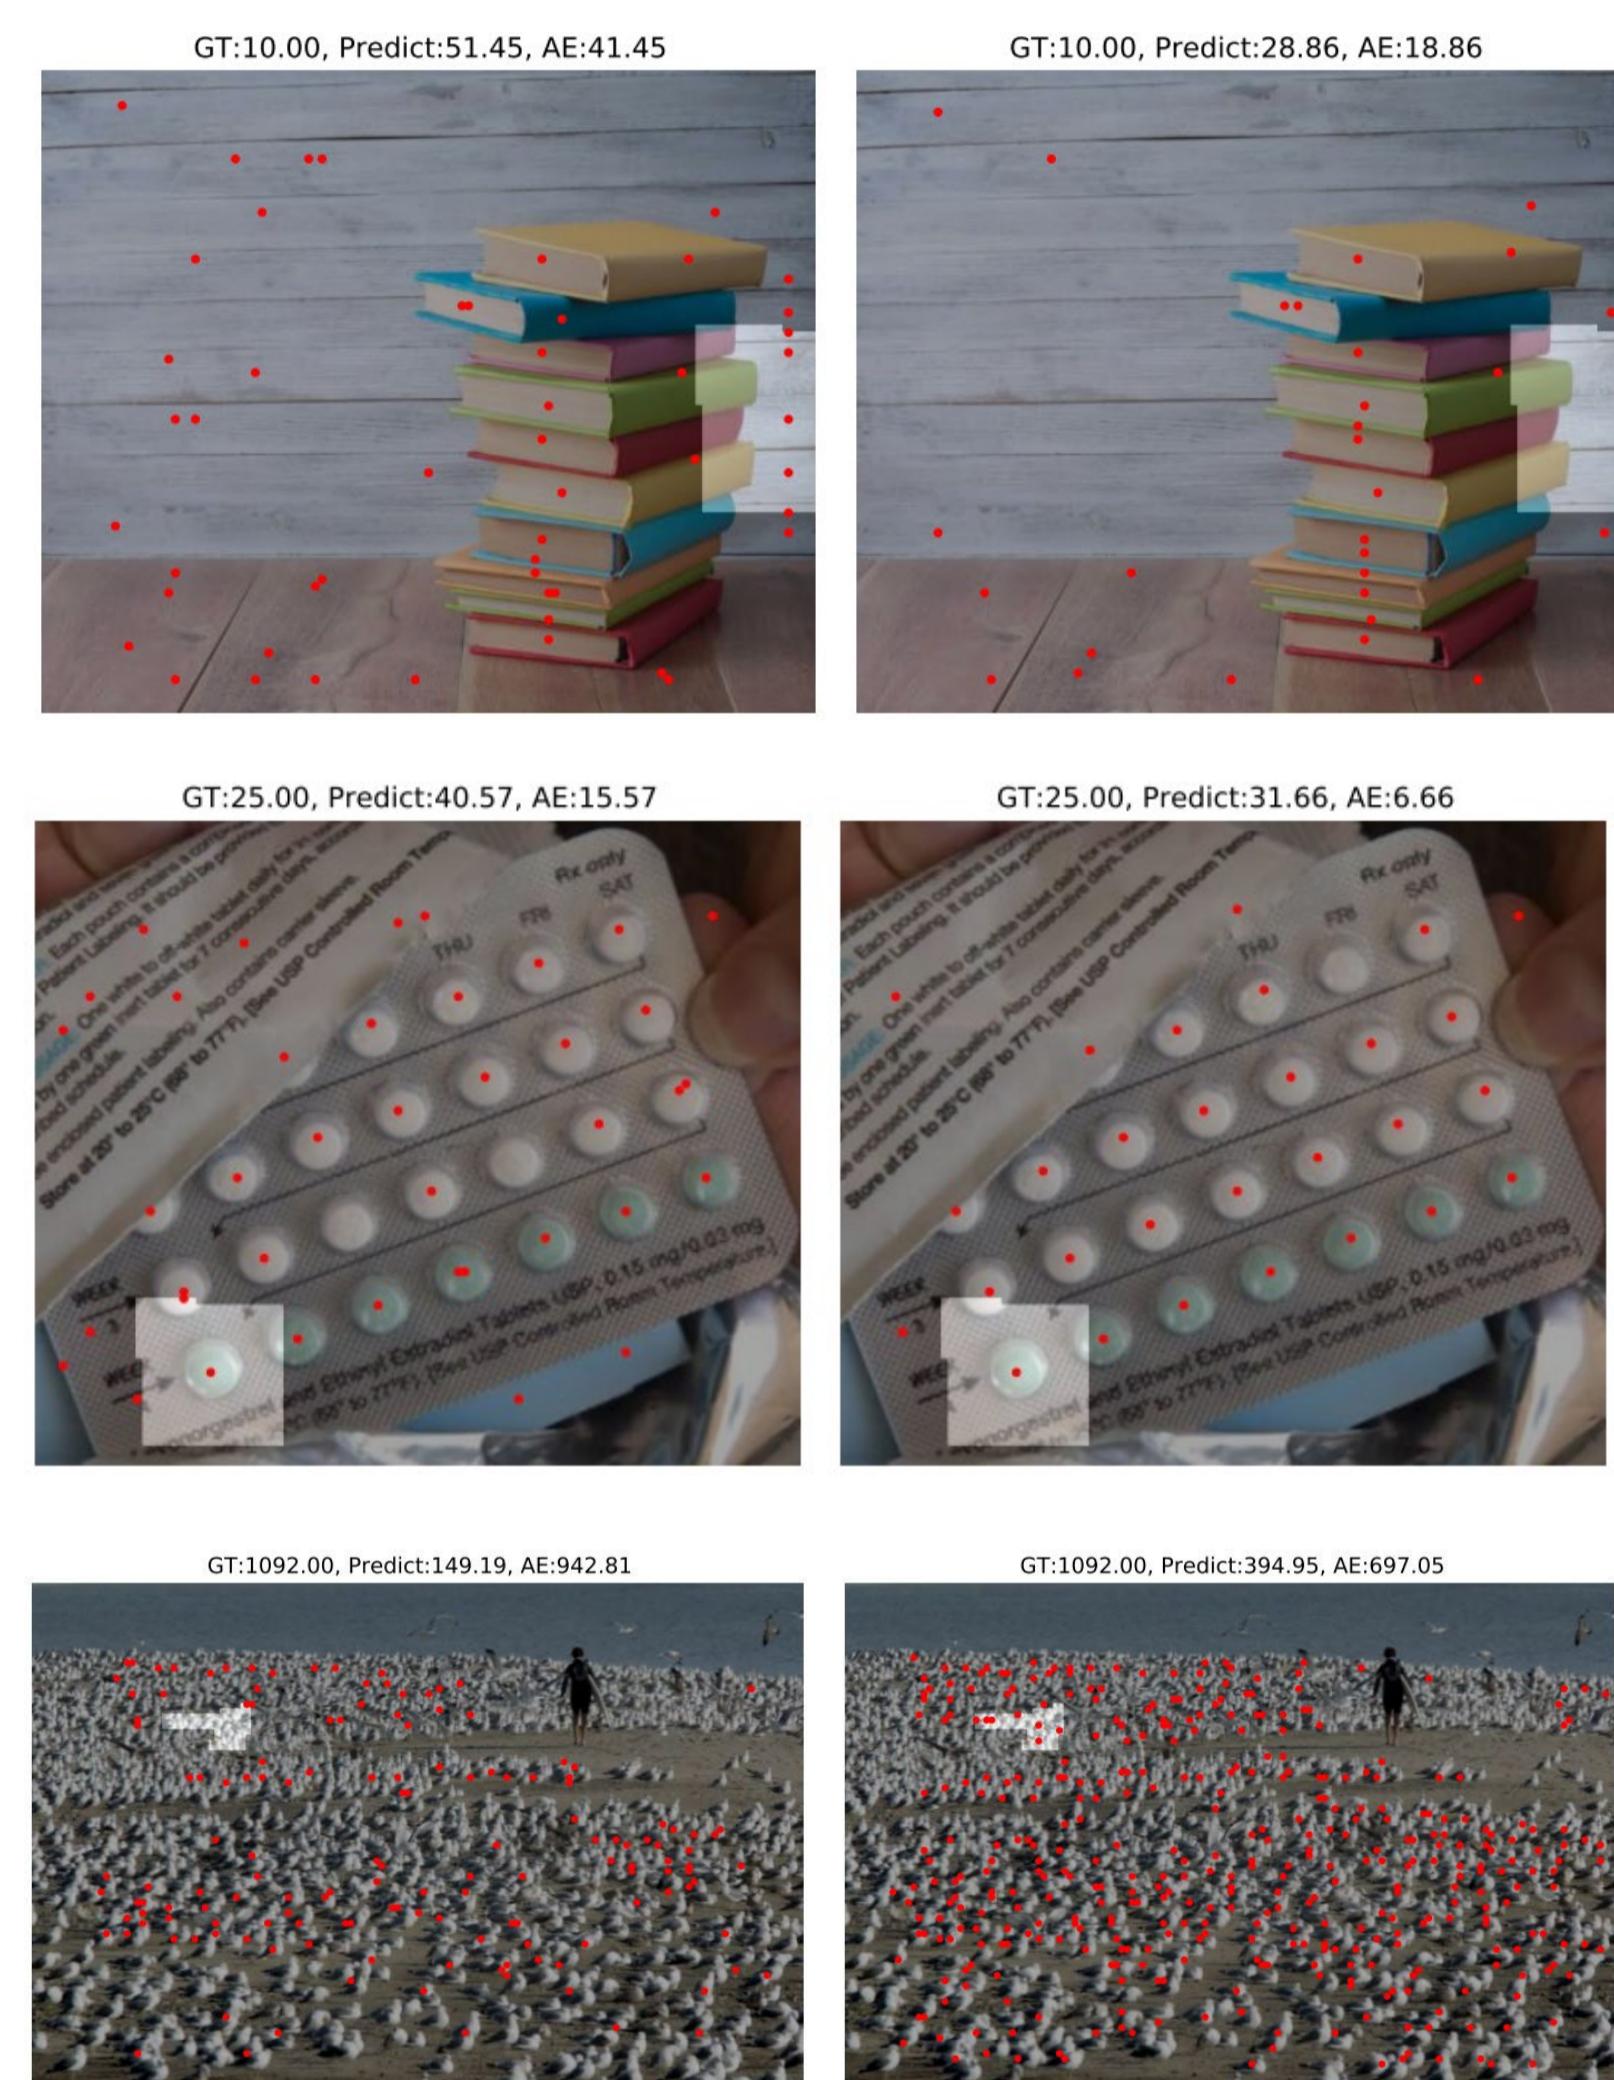

- **Adaptation:** We only update the parameters in feature refinement module. We also adjust learning rate and adaptation steps with the confidence in feedback.

$$\text{Adaptation Loss: } \mathcal{L}(\Omega) = \mathcal{L}_L(\Omega) + \mathcal{L}_G(\Omega) + \eta(||\theta^{scale} - 1|| + ||\theta^{bias}||)$$

Result

Qualitative result: the left is before interaction. The highlighted region is the selected region.

	FSC-147 Test Set	FSCD-LVIS Test Set		
	MAE	RMSE	MAE	RMSE
